The invention relates to a method for detection of nucleic acid (I)

having at least 2 portions, comprising treatment with nanoparticles that

carry oligonucleotides complementary to at least 2 parts of (I), where

detectable change caused by hybridisation of the oligonucleotide to (I)

is observed. The method is used to detect (or to separate) specific (I),

e.g. for diagnosing a wide variety of diseases, sequencing, in forensic

analysis etc., and generally to detect analyses other than (I). The

cligonucleotide-derivatised nanoparticles are also useful for preparing

nanostructures useful, for example, as biochips, biofilters, mechanical

devices, separation membranes, chemical sensors, in computers, and for

drug delivery. Very stable nanoparticle-oligonucleotide conjugates

can be produced, allowing their direct use (as probes) in polymerase

can be produced after amplification. (I) are detected by simple

colour change, without the need for special equipment, making possible

rapid field testing for e.g. pathogens. AAS631374-AAS63448 represent

colour change, has invariable probes, and related sequences, used in the

mathod of the advance of the colour probes, and related sequences.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Oligonuclectide-nanoparticle probe; diagnostic; forensic analysis; nucleic acid detection; nanostructure; biochip; biofilter;
               Detecting and separating nucleic acid, useful e.g. for diagnosis, comprises reaction with nanoparticles that carry oligonucleotides
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Mucic RC, Storhoff JJ, Elghanian R;

The invention relates to a method for detection of nucleic acid (I) having at least 2 portions, comprising treatment with nanoparticles that carry oligonucleotides complementary to at least 2 parts of (I), where caused by hybridisation of the oligonucleotide to (I) is observed. The method is used to detect (or to separate) specific (I), e.g. for diagnosing a wide variety of diseases, sequencing, in forensic analysis etc., and generally to detect analyses other than (I). The oligonucleotide-derivatised nanoparticles are also useful for preparing nanostructures useful, for example, as biochips, biofilters, mechanical devices, separation membranes, chemical sensors, in computers, and for devig delivery. Very stable nanoparticle-oligonucleotide conjugates can be produced, allowing their direct use (as probes) in polymerase chain reaction, ie. they survive multiple heating/cooling cycles so do not need to be added after amplification. (I) are detected by simple colour change, without the need for special equipment, making possible rapid field testing for e.g. pathogens. AAS63174-AAS63448 represent coligonucleotide-nanoparticle probes, and related sequences, used in the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Nanoparticle, oligonucleotide, DNA detection, DNA isolation, genetic disease, bacterial disease, viral disease, forensic science, paternity testing, gene therapy, ss.

The sequence represents an oligomucleotide which is linked by its 3' end to a nanoparticle. The sequence is complimentary to a target oligomucleotide. The nanoparticle may be linked to several oligomucleotides. The nanoparticle may be linked to several oligomucleotides. The sequence is used to demonstrate the method of the invention. The invention relates to isolating or detecting a moleic acid finterset, in a mixture of mucleic acids, by binding it to 2 or more complimentary nuclectides which have a nanoparticle attached to their 5' ends. The nanoparticles (e.g. colloidal gold) are used to both isolate complimentary nuclectides which have a nanoparticle attached to their 5' ends. The manoparticles (e.g. colloidal gold) are used to both isolate or and detect (e.g. by linking the particle to a fluorescent probe) the resultant complex. The methods are useful for detecting nucleic acids, natural or synthetic, and modified or unmodified. The methods may also be applied in the diagnosis of genetic, bacterial and viral diseases, in for monitoring gene therapy. The methods are further useful in research and analytical laboratories in DNA sequencing, in the field to detect the presence of specific pathogens; cor quick identification of an infection to assist in drug prescription, and in homes and health centres for inexpensive (irst-line screening. The methods, which are based on observing classified and little or no instrumentation; and ill homes and the surface specialised or expensive equipment, and little or no instruments of require specialised or expensive equipment, and little or no instruments.
                                                                                                                                                                                                                                                                                                      Detecting a nucleic acid useful in e.g. diagnosing genetic, bacterial or viral diseases, by contacting the nucleic acid with oligonucleotides attached to nanoparticles and having sequences complementary a portion
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Nanoparticle, oligonuclectide; DNA detection; DNA isolation;

The sequence represents an oligomuclectide which is linked by its 3' end to a nanoparticle. The sequence is complimentary to a target of to a nanoparticle. The sequence is complimentary to a target oligomuclectides. The nanoparticle may be linked to several oligomuclectides. The nanoparticle may be linked to several twention. The invention relates to isolating or detecting a nucleic acid of interest, in a mixture of mucleic acids, by binding it to 2 or more complimentary nuclectides which have a nanoparticle attached to their 5' ends. The nanoparticles (e.g. colloidal gold) are used to both isolate complimentary nuclectides which have a nanoparticle attached to their 5' and detect (e.g. by linking the particle to a fluorescent probe) the cresultant complex. The methods are useful for detecting nucleic acids, natural or synthetic, and modified or unmodified. The methods may also be complied in the diagnosis of genetic, bacterial and viral diseases, in formatication, and for monitoring gene therapy. The methods are uthentication, in the field to detect the presence of specific pathogens, sequencing, in the field to detect the presence of specific pathogens, or prescription, and in homes and health centres for inexpensive colour change with the naked eye, are cheap, fast, simple, robust and little or no instrumentation is require specialised or expensive equipment, and illetine mand the properties of an infection to assist in drug
                                                                                                                                                                                                                                                                                                                                                                                                                             Detecting a nucleic acid useful in e.g. diagnosing genetic, bacterial or viral diseases, by contacting the nucleic acid with oligonucleotides attached to nanoparticles and having sequences complementary a portion of the nucleic acid.
/note= "A is covalently linked to a colloidal gold
particle"
                                                                                                                                                                                                                                                                                                                                Mucic RC, Storhoff JJ, Elghanian R;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Nucleic acid detection; nanoparticle-oligonucleotide conjugate;

The method comprises hybridising the nucleic acid with Oligonucleotides, such as the present sequence, attached to a substrate and/or particle and detecting a change in colour, conductivity or optical density. The method is useful for the diagnosis and/or monitoring of diseases, in forensics, in DNA sequencing, for paternity testing, for cell line authentication and for monitoring gene therapy. Detecting nucleic acids based upon observing a colour change is cheap, fast, simple, and does not require specialised or expensive equipment. The nanoparticle oligonucleotide conjugates remain stable for at least 6 months. A single base mismatch and as little as 20 femtomoles (fM) of target can be detected using the conjugates.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  Nucleic acid detection; nanoparticle-oligonucleotide conjugate;

The invention discloses methods for removing silver from a silver stained DNA detection chip having bound gold nanoparticles, which comprises using ac oyanide etching solution or ultrasound waves. The chip based DNA detection method employs gold nanoparticle probes, modified with comprises to indicate the presence of a particular DNA sequence of igonuclectides, to indicate the presence of a particular DNA sequence thybridised on a transparent substrate in a three component sandwich assay format. Initially the capture oligonuclectide is immobilised onto a glass substrate. The target oligonuclectide is then hybridised to the capture oligonuclectide is then hybridised to the capture componential probes functionalised with target-complementary DNA. The signal can be enhanced, creating trees of nanoparticles, which can be consuming the chap especial sective and sensitive, but the re-use of the chips depended on the complete removal of the stain without damaging the chip. The advantage of these removal of the stain cre-cycled and re-used. The sequence presented is the capture of re-cycled and re-used. The sequence presented is the capture

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       The present sequence is an oligonucleotide used in a method for detecting a nucleic acid having at least 2 portions. The method comprises hybridising the nucleic acid with holigonucleotides, such as the present sequence, attached to a substrate and/or particle and detecting a change in colour, conductivity or optical density. The method is useful for the diagnosis and/or monitoring of diseases, in forensics, in DNA sequencing, for paternity testing, for cell line authentication and for monitoring gene therapy. Detecting nucleic acids based upon observing a colour change is cheap, fast, simple, and does not require specialised or expensive equipment. The nanoparticle oligonucleotide conjugates remain stable for at least 6 months. A single base mismatch and as little as 20 femtomoles (fM) of target can be detected using the conjugates.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Detecting nucleic acid, useful for e.g. diagnosis of diseases, forensics and DNA sequencing, comprises observing detectable change brought about by hybridization of nucleic acid with substrate or particle bound oligonucleotides -

Nucleic acid detection method associated polynucleotide #73.

Nucleic acid detection method; nanoparticle-oligonucleotide conjugate;

```
The invention describes a method of detecting (MI) a nucleic acid having two portions, involving providing nanoparticles having oligomucleotides attached to it, which has a sequence complementary to sequence of two portions of nucleic acid, contacting nucleic acid and nanoparticles, to portions of nucleic acid, and nanoparticles, to allow hybridisation of oligomucleotides with two or more portions of hybridisation. (MI), nanoparticles (I), nanoparticles by the hybridisation (MI), nanoparticles (I), nanoparticles (I), nanoparticle-oligomucleotide conjugates (II) and the aggregate probe are useful for detecting two or portions, such as viral RNA, bacterial or fungal DNA, a gene associated with a disease, synthetic, or structurally-modified natural or synthetic (II) is useful for preparing a nanoprobe conjugate for detecting an analyte, and for detecting a nucleic acid having two portions from other nucleic acids (I), (II) and conversable or detecting an analyte (especially natural mania) assertly for fabrication, and for separating a selected the aggregate probe are useful for detecting an analyte (especially natural mania).
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Detecting nucleic acid having two portions, by providing nanoparticles having oligonucleotides attached to it, contacting nucleic acid and nanoparticles to allow hybridization, and observing detectable change
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Gaps
                                                                                                                                                                                                                                                                                                                                                                                                            Letsinger RL, Mucic RC, Storhoff JJ, Elghanian R; Garimella V, Li Z, Park S;

at least 2 portions comprising: (a) providing another actual New, may have at least 2 portions comprising: (a) providing nanoparticles (NP) with attached oligonucleotides (OGN), where OGN has a sequence complementary control to the sequence of NA; (b) contacting NA and NP under conditions of effective to allow hybridisation of OGN with NA; and (G) observing a detectable change brought about by hybridisation of OGN with NA.

The method is useful for detecting a nucleic acid, separating a selected nucleic acid from others and methods of nanofabrication.

Detecting analytes such as nucleic acids and proteins are useful for the diagnosis of genetic, bacterial and viral diseases. The OGN-NP conjugates that use cyclic disulphide linkers improve the sensitivity of diagnostic assays. In particular assays using OGN-NP conjugates prepared using completes comprising a staroid residue attached to a cyclic disulphide have been found to be approximately 10 times more sensitive than assays employing conjugates prepared using a state linker. The OGN-NP conjugates are stable allowing them to be used directly in PCR solutions. Therefore conjugates as probes to a DNA target to be PCR annulified can be carried through the 30 or 40 heating colling cycles of the PCR and are still able to detect the amplicons represent mannary and causing contamination. ```
The invention relates to a method of detecting a nucleic acid (NA) having at least 2 portions comprising: (a) providing nanoparticles (NP) with at least 2 portions comprising: (a) providing nanoparticles (NP) with a traded oligonucleotides (OGN), where OGN has a sequence complementary content of NA; (b) contacting NA and NP under conditions of the sequence of NA; (b) contacting NA and NP under conditions of detectable change brought about by hybridisation of OGN with NA.

CC detectable change brought about by hybridisation of OGN with NA.

The method is useful for detecting a nucleic acid, separating a selected nucleic acid from others and methods of nanofabrication.

CC diagnosis of genetic, bacterial and wiral diseases. The OGN-NP conjugates that use cyclic disulphide linkers improve the sensitivity of diagnostic that use cyclic disulphide linkers improve the sensitivity of diagnostic linkers comprishing a steroid residue attached to a cyclic disulphide have semploying conjugates prepared using alkanethiols or acyclic disulphides of irrectly in PCR solutions. Therefore conjugates added as probes to a DNA cooling cycles of the PCR and are still able to detect the amplicas without opening the tubes and causing contamination. ABK65055

the invention retailes to a method or detecting a nucleic acid (NA) having at least 2 portions comprising: (a) providing nanoparticles (NP) with attached oligonucleotides (OGN), where OGN has a sequence complementary concludes the sequence of NA; (b) contacting NA and NP under conditions of effective to allow hybridisation of OGN with NA; and (C) observing a detectable charge brought about by hybridisation of OGN with NA.

The method is useful for detecting a nucleic acid, separating a selected nucleic acid from others and methods of nanofabrication.

C diagnosis of genetic, bacterial and viral diseases. The OGN-NF conjugates that use cyclic disulphide linkers improve the sensitivity of diagnostic that use cyclic disulphide linkers incomprising a steroid residue attached to a cyclic disulphide have sensitive than assays comportising a steroid residue attached to a cyclic disulphide have employing conjugates prepared using alkanethicles or acyclic disulphides of inkers comprising a steroid residue attached to a cyclic disulphides conjugates prepared using alkanethicles or acyclic disulphides as the linker. The OGN-NF conjugates are stable allowing them to be used directly in PCF solutions. The referee conjugates added as probes to a DNA carried through the 30 or 40 heating colling cycles of the PCR and are still able to detect the amplicons without popular or peaning or action or acti

This invention describes a novel method of detecting nucleic acid having at least two portions. The method involves providing nanoparticles attached to oligomuclectides, where the oligomuclectide on each canoparticle have a sequence complementary to a sequence of at least two portions of nucleic acid, contacting nucleic acid and nanoparticle to callow hybridisation of the oligomuclectide on the nanoparticle to callow hybridisation of the oligomuclectide on the nanoparticle with two or more portions of nucleic acid and observing a detectable change or uncleic acid. The method is useful for separating a selected nucleic acid the aving at least two portions, from other nucleic acids and for acid having at least two portions. The method is useful for detecting any type of nucleic acids which may be used for diagnosis of disease and in sequencing of nucleic acids. Preferably, the method is useful for detecting nucleic acids for diagnosis and/or monitoring of viral infections (human immundeficiency virus (HIV), hepatitis virus, herpes virus, cytomegalovirus and Epstein-Barr virus), bacterial diseases, sexually transmitted diseases, inherited diseases, acuthentication, and for monitoring of the presencing, in the field to cresarch and analytical laboratories in DNA sequencing, in the field to non whenevirus and specialic pathogons. Detecting nucleic acids based on whenevirus and special pathogons. Detecting nucleic acids acids hased
                                                                                                        Nonoparticle, nucleic acid detection, hybridisation, diagnosis, sequencing, viral infection, human immunodeficiency virus, HIV; hepatitis virus, herpes virus, cycomegalovirus, Bpstein-Barr virus, bacterial infection, sexually transmitted disease; inherited disorder; forensic; paternity testing; cell line authentication; gene therapy; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  detect the presence of specific pathogens. Detecting nucleic acids base on observing a colour change with the naked eye is cheap, fast, simple and robust and does not require specialised expensive equipment. ABX92123-ABX92186 and ABQ77356 represent oligonucleotides used to
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Detecting nucleic acids having at least two portions involves use of nanoparticles which have oligonuclectides attached to them that are complementary to portions of the nucleic acid sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Mirkin CA, Letsinger RL, Mucic RC, Storhoff JJ, Elghanian R,
                                                                  Nanoparticle-associated oligonucleotide SEQ ID 43.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        illustrate the method of the invention.

(NANO-) NANOSPHERE INC.

Mucic RC, Storhoff JJ, Elghanian Letsinger RL, Mirkin CA, Taton TA;

Detecting nucleic acids having at least two portions involves use of nanoparticles which have oligonuclectides attached to them that are complementary to portions of the nucleic acid sequence WPI; 2003-182627/18.

Example 17; Figure 26; 130pp; English.

This invention describes a novel method of detecting nucleic acid having at least two portions. The method involves providing nanoparticles at least two portions. The method involves providing nanoparticles at least two can properticle to an apparence of at least two portions of mucleic acid, contacting nucleic acid and nanoparticle to allow hybridisation of the oligonucleotide on the nanoparticle with two cor more portions of mucleic acid and observing a detectable change brought about by hybridisation of the oligonucleotide nanoparticle with two correct two portions. The method is useful for separating a selected nucleic acid acids. The method is useful for separating a selected nucleic acid acids having at least two portions. The method is useful for detecting any type of mucleic acids which may be used for diagnosis of disease and in sequencing of nucleic acids. Preferably, the contioning of viral infections (numan immunodeficiency virus (HIV), hepatitis virus, herpes virus, cytomegalovirus and Epstein-Barr virus), concerning diseases, sexually transmitted diseases, inherited disorders, in forensics, in DNA sequencing, for paternity testing, for cell line research and analyticial laboratories in DNA sequencing, in the field to authentication, and for monitoring gene therapy. The method is useful in cesearch and analyticial pathogens. Detecting nucleic acids based on observing a colour change with the naked eye is cheap, fast, simple conditional adoes not require specialised expensive equipment. illustrate the method of the invertion.

The OG on each tamoparticle have a sequence complementary to the sequences of at least two portions of the nucleic acid being detected. Contacting between the hybridisation conditions, where binding is detected via a colour change. The method has applications in diagnosis of a diseases (e.g. diagnosing and monitoring viral diseases and as eystic fibrosis, cancers, etc.), in sequencing of authentication and for monitoring gene therapy. This sequence represents a DNA associated with the nucleic acid detection method of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           nanoparticles, where each oligonucleotide has a sequence complementary to at least two portions of the nucleic acid being detected, useful in diagnosis of a diseases (e.g. HIV)

The invention describes a method of detecting a nucleic acid using objeonucleotides (OG) attached to nanoparticles. The OG on each nanoparticle have a sequence complementary to the sequences of at least two portions of the nucleic acid being detected. Contacting between the handparticle conjugated OG and nucleic acids takes place under hybridisation conditions, where binding is detected via a colour change. The method has applications in diagnosis of a diseases (e.g. diagnosing and monitoring viral diseases such as HIV, bacterial diseases, inherited nucleic acids, in forensics, for paternity testing, for cell line authentication and for monitoring gene therapy. This sequence represents a DNA associated with the nucleic acid detection method of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    complementary

Detecting nucleic acids having at least 2 portions comprises use of nanoparticles which have oligonucleotides attached to them that are complementary to portions of the nucleic acid sequence.

Example 17; Fig 26; 130pp; English.

The invention relates to detecting a nucleic acid (NA) having at least 2 portions, comprises providing a type of nanoparticles (NP) having attached to oligonucleotides (O) (O) on each NP has a sequence of at least 2 portions of NA), contacting NA and observing a detectable change brought about by hybridisation of (N), on NP with 2 or more portions of NA, and observing a detectable change brought about by hybridisation of (N) on NP with NA. The nanoparticle is useful for separating a selected nucleic acid having at least 2 portions, the method of respecting nucleic acids having at least 2 portions. The method of using NP is useful for detecting any type of nucleic acids, and the method of using NP is useful for detecting any type of nucleic acids for used for diagnosis of disease and in sequencing of nucleic acids for preferably, the method is useful for detecting nucleic acids for diagnosis and/or monitoring of viral diseases (human immunodeficiency virus, bepatitis virus, herpes virus, cytomegalovirus and Epstein-Barr CC virus, bacterial diseases, sexually transmitted diseases, inherited diseases, in forensics, in DNA sequencing, for cell line authentication and for monitoring gene therapy. The method is consecuted in research and analytical laboratories in DNA sequencing and in the field to detect the presence of specific pathogens. Detecting nucleic acids based on observing a colour require specialised expensive equipment. The present sequence is a nanoparticle (e.g. gold

Clones are arrayed into multi-well plates. Each well contains 16 oligonucleotides with a 5 polylinker, a poly-T run capable of binding cDNAs by their poly-A tail and a unique 3' sequence, which allows an anchored oligonucleotide in each complementary 5' end. The unique 3' key sequences are designed to give a comprehensive level of degeneracy since they are diverse and numerous enough to ensure that every possible cDNA sequence can be bound by an individual, specific oligonucleotide in a single well. The cDNA library is heated to denature the clones into single stranded DNA, and an aliquot is added to every well. The anchored cligonucleotide serves as the 3' primer in PCR, and the common 5' oligonucleotide serves as the 3' primer in PCR, and the common 5'
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Identifying nucleic acid encoding novel sex-linked-tissue-linked receptors, useful for isolating odorant binding proteins or pesticide alternatives, by analyzing sequences from a male- and female-specific nucleic acid library
                                                                                                                                                                                                                                                                                           Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       present sequence is that of an oligonucleotide used in a method
particles) labelled probe used to demonstrate the method of the invention. In this case the oligonucleotides are immobilised onto semiconductor nanoparticle quantum dots.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          G-protein coupled receptor; odourant; receptor; olfaction; array; microarray; anosmia; attractant; arometic; pesticide; PCR; primer;

0
region present in every CDNA clone serves as the 5' priming site.

Denaturing and washing leave anchored CDNA in each well. The library is now arrayed and normalised. The method was used to identify and isolate clones encoding G-protein coupled receptors, especially odourant receptors, and active effectors involved in the olfactory pathway of invertebrates and vertebrates, e.g. odourant binding proteins, or other olfactory neuronal proteins. The identified receptors and proteins are useful for identifying compounds that reduce a target animal's sensitivity to odours, for manufacturing compounds or devices that mask odours, or trapping invertebrates with odourants. Semiochemicals (e.g. arometics or pheromone mimetics) can be developed with desirable effects on specific species for the development of pest monitoring systems or non-toxic, species-specific pesticide alternatives, for controlling insect feeding and breeding behaviour, detecting the presence of small air-borne molecules, etc.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        This invention describes a novel method for analysis of an RNA sample which comprises amplifying cDNA with first and second differently labeled primers and analysis of the amplified labeled cDNA. The method is useful for analyzing differential gene expression, for identifying and/or characterizing pharmacological activities or for identifying target genes. The use of different primer combinations allow more cDNAs to be amplified. The method also provides a more detailed analysis than prior art methods. This sequence represents a primer used to illustrate the method of the invention.

Sequences were determined from the ends of chromosome 11-specific cosmids by automated sequencing without intermediate subcloning. A sample of 371 DNA sequence fragments were determined and of these, 277 were suitable for STS primer prediction by computer analysis (using the "Primer" program available from E. Lander, MIT). The STSs and cosmids were mapped by in situ hybridisation, somatic cell hybrid analysis or both. Using this method, 370 STSs specific for human chromosome 11 were generated and most of them were regionally mapped. This procedure illustrates a novel method for sequencing complex genomes, designated "sequence sampled mapping method is useful for the completion of high density sequence-based maps, and ultimately, for the complete complete complete.
                                                                                                                                                                                                                                                       sequence sampled mapping; genomic analysis; complex genome mapping; cosmid library; chromosome 11; sequence tagged site; STS analysis; ss.

The invention training to the number of G69120) which encoded it. ABCT is a member of the ATP-binding cassette (ABC transporter) superfamily of proteins, and plays a crucial role in cholesterol transport, particularly of intracellular cholesterol trafficking in monocytes and fibrohasts, being conversellular cholesterol trafficking in monocytes and fibrohasts, being involved in cholesterol trafficking in monocytes and fibrohasts, being closated on chronesome 991, and mutations in this gene are associated with two genetic HDL (high density lipoprotein) deficiency disorders, rangier disease (TD) and familial HDL deficiency (FRA). These diseases of fatinguishable in that TD is an autosomal recessive disorder, while cholesterol') in the blood correlate with a high risk of cardiovascular disease, coronary reteronary artery disease, but also cerebrovascular disease, coronary restences is a protective effects against constructs and transpence cells and non-human animals comprising human ABCI nucleic cardiovascular disease compounds of gene therapy for the treatment or prevention of acide, and methods of gene therapy for the treatment or prevention also recompasses compounds which mimic ABCI extreming whether a patient has an encompassed risk for cardiovascular disease compounds which mimic ABCI activity, compounds which compounds increased risk for cardiovascular disease can parient has an encompassed risk for cardiovascular disease can be used to polymorphisms in the

The invention specifically excludes proteins with the exact amino acid sequences of GenBank Accession No: CAA10005.1 and X75926, and the nucleic acid with the exact sequence as GenBank Accession No: AJ012376.1. The present sequence represents a polymorphic site of the human ABC1
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        polypeptide. RIP60 is a zinc finger protein. The nucleic acid binding domain of the RIP60 polypeptide is used to construct a non-viral nucleic acid delivery complex comprising a modular non-viral nucleic acid delivery complex comprising a modular poptide. The complex comprises a modular peptide containing a nucleic acid binding domain and a nucleic acid condensation domain and a nucleic acid condensation domain condenses in length. The complex also comprises one or more solvipoptides selected from a cell recognition domain, a protein transduction domain, a protein interaction domain, an intracellular transduction domain, a protein interaction domain, an epitope domain and a protein purification domain. The complexes are used to deliver a nucleic acid to a cell. The nucleic acids delivered are of various sizes and preferably greater than 50 kilobases, especially more than
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    Non-viral nucleic acid delivery complex for delivering a nucleic acid molecule into a cell comprises a modular polypeptide -
                                                                                                                                                                                                                                                                                                                                                                                                                                            Nucleotide sequence which is bound by 22 domain of RIP60 polypeptide.
                                                                                                                                                                                          Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Human; RIP60; zinc finger protein; nucleic acid delivery complex;

The invention relates to a novel Disrupted-In-Schizophrenia (DISC) 1 allelic variant polynucleotide. The polypeptides of the invention have neuroleptic activity. The polynucleotides may have a use in gene therapy. DISC1 or DISC2 nucleic acid molecules are useful for diagnosing or Lreating a subject having a disease or disorder associated with specific DISC1 or DISC2 alleles and/or aberrant DISC1 expression or activity e.g. neuropsychiatric disorder such as schizoaffective, bipolar, unipolar affective or adolescent conduct disorder or schizophrenia. Similarly, affective or adolescent conduct disorder or schizophrenia. Similarly, method for treating such neuropsychiatric disorders. The sequences shown in ABQ93575-ABQ93658 represent the PCR primers used in the invention to amplify the sequences of DISC2 and DISC2.
                                                                                                                                                                                                                                        Human; Disrupted In Schizophrenia 1; DISC1; neuroleptic; gene therapy; neuropsychiatric disorder; schizoaffective disorder; bipolar disorder; unipolar affective disorder; adolescent conduct disorder; schizophrenia; PCR; primer; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 New human Disrupted-In-Schizophrenia (DISC) 1 and DISC2 genes containing single nucleotide polymorphisms, useful for preventing or treating neuropsychiatric disorders e.g. schizophrenia
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Gaps

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The present invention relates to methods for distinguishing between individuals homozygous for and therefore afflicted with Van Buchem's disease, individuals heterozygous for and therefore carriers of Van Buchem's disease comprise identifying a large genomic deletion in chromosome 17 at 17q21. The method is useful for identifying individuals who are afflicted with or carriers of diseases associated with one or more genomic deletion, particularly Van Buchem's disease, which is a rare autosomal recessive disorder that results in a bone dysplasia referred to a craniotubular hypertosis. The present sequence is a PCR primer used to amplify 92Kb gene fragment in human chromosome 17 at 17q21.

The present invention relates to methods for distinguishing between individuals homozygous for and therefore afflicted with Van Buchem's disease, individuals hererozygous for and therefore carriers of Van Buchem's disease and individuals who are not afflicted with Van Buchems's disease comprise identifying a large genemic deletion in chromosome 17 at 17q21. The method is useful for identifying individuals who are afflicted with or carriers of diseases associated with one or more genomic deletion, particularly Van Buchem's disease, which is a rare autosomal recessive disorder that results in a bone dysplasia referred to a cranicubular hypertosis. The present sequence is a PCR primer used to amplify 92Kb gene fragment in human chromosome 17 at 17q21.
                                                                                                                                                                                                                                 Methods for identifying subjects who are afflicted with or carriers of diseases associated with genomic deletion(s), e.g. Van Buchem's disease, by determining the presence of a deletion in the 92 kb region of human chromosome 17 at 17q21
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Oestrogen receptor hammerhead ribozyme target sequence SEQ ID NO:1950.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Oestrogen receptor; c-raf; k-ras; bcl-2; ribozyme; cleavage; hammerhead ribozyme; hairpin ribozyme; antisense oligonuclectide; gene expression modification; cancer; phosphorothicate; endonuclease;

The present invention describes nucleic acids (A) that interact stably with a target sequence and contain at least one phosphoro(di)thioate link, having endonuclease activity. (A), and more generally any catalytic nucleic acid (A') that modulates expression of the oestrogen receptor gene, are used to treat cancer (particularly of breast or receptor gene, are used to transforming cells ex vivo and implanting transforming cells ex vivo and implanting conference conditions associated with levels of the conference conditions associated with levels of alterations in phenotype, particularly for identification of therapeutic targets, and as research reagents (for RNA, in the same way that restriction endonucleases are used with DNA). The combination of and/ifications in (A) improves resistance to nucleases, binding affinity and/ifications in (A) improves resistance to nucleases, binding affinity and/or activity. AAA23503 to AAA24748 to AAA25992 represent their corresponding target sequences, and AAA25107 to AAA2519 represent cheir orresponding target sequences. AAAA5519 to AAA26107 represent their receptor hairpin ribozyme sequences. AAAA5519 to AAA2617 represent their corresponding target sequences. AAAA56107 to AAA2618 represent their corresponding target sequences. AAAA56107 to AAA2617 represent their corresponding target sequences. AAAA2619 to AAA26271 represent their corresponding target sequences. AAAA2619 to AAA2617 represent their corresponding target sequences. AAAA26107 to AAA2617 represent their corresponding target sequences. AAA26191 to AAA2617 represent their corresponding target sequences. AAA26107 to AAA2617 represent their exemplification of the present invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   ó

with a target sequence and contain at least one phosphoro(di)thioate link, having endonuclease activity. (A), and more generally any catalytic nucleic acid (A') that modulates expression of the oestrogen receptor gene, are used to treat cancer (particularly of breast or receptor gene, are used to treat cancer (particularly of breast or receptor gene, are used to treat cancer (particularly of breast or conductions associated with levels of casted cells, or for other conditions associated with levels of can also be used to correlate inhightion of gene expression with contractions in phenotype, particularly for identification of therapeutic targets, and as research reagents (for NA, in the same way that restriction endonucleases are used with DNA). The combination of and/or activity. AAA23503 to AAA24748 to AAA25992 represent their corresponding target sequences, and AAA25107 to AAA25192 represent their corresponding target sequences, and AAA25107 to AAA2518 represent centrogen receptor alripin ribozyme sequences. AAA25993 to AAA26107 to AAA2511 represent their corresponding target sequences. AAA25991 to AAA2611 represent their corresponding target sequences. AAA25991 to AAA2611 represent centrogen receptor alripin ribozyme sequences. AAA25991 to AAA2611 represent corresponding target sequences. AAA25991 to AAA2611 represent centrogen corpus ribozyme sequences. AAA25991 to AAA26211 represent corpus corpus and antisense oligonucleotides used in the
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               0;
                                                                                                                                                                          present invention describes nucleic acids (A) that interact stably
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Sequential consensus region-directed amplification for sorting mixture of DNAs into 2 or more subsets or distinguishing gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Oligo-AT PCR primer #2 used to illustrate the method of the invention.

The invention relates to a method of segmential consensus region-directed amplification for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples. The methods, kits and oligonucleotides are useful for sorting a mixture of DNAs into 2 or more subsets or distinguishing gene expression patterns in 2 samples e.g. for disease diagnosis and gene analysis. The present sequence is oligo AT PCR primer used to illustrate the method of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Probes for detecting target nucleotide sequence in sample, has sequence that forms hairpin structure having a double-stranded segment and single-stranded loop collectively forming region complementary to
 in 2 samples, useful for disease diagnosis and gene analysis
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      The present sequence is that of DNA-RNA-DNA hybrid oligonucleotide AGT02014. This is one of a set of oligonucleotides (see ABBA91527-30) used to assess the minimum number of ribonucleotides in DNA-RNA chimeric oligonucleotides required for RNase H cleavage. Each oligonucleotide of the set had a different number of ribonucleotides, in the present case. The oligonucleotides were mixed with target DNA oligonucleotide AGT02009 (see ABA91531) and incubated with RNase H (5 U/Ml) at 37 degrees C for 30 minutes. The results showed that 4 ribonucleotides were the minimum number
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         DNA-RNA-DNA oligonucleotide AGT02014 used to test RNase H cleavage.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           DNA-RNA hybrid; RNase H; nucleic acid detection; ss.

for RNA cleavage. The invention provides probes for nucleic acid hybridisation. The probes form a hairpin structure comprising a double-stranded stem and a single-stranded loop, and are capable of both intramolecular and intermolecular hybridisation. The double-stranded stem may comprise a methylphosphonate DNA:RNA hybrid that is resistent to RNAse H Gleavage. When the probe hybridises with a target DNA, the RNA strand in the DNA:RNA duplex becomes sensitive to RNase H treatment and can be removed. Arrays and methods for nucleic acid hybridisation using the probes are provided.
                                                                                                                                                                                                      Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                       deoxyribonucleic acid; major groove; ethanoamino group; tumour necrosis factor; receptor; messenger RNA; aziridinylcytosine;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 The oligomer was designed to target human TNF receptor mRNA beginning at nucleotide 2354 and to covalently cross-link to the target via the N4N4-ethanocytosine group. The sequence depicts a HUMNFR (tumour necrosis factor receptor) mRNA sequence obeginning at nucleotide 2354. The sequence is a viral duplex sequence contg. a purime-rich region concentrated on one chain of the duplex. The sequence may be prepd. by standard DNA synthesis. The tumner are dapable of forming a triplex at physiological pH by coupling into are capable of forming a triplex at physiological pH by coupling into the major groove of the DNA duplex. Three such oligomers WIRP 941-22 are capable of forming a triplex with this sequence. The oligomers may be used to target viral DNA duplexes specific for HIV, herpes and cher viruses. The triple helices form under mild conditions thus assays may be carried out without subjecting the test specimen to harsh conditions. The oligomer is able to inhibit gene expression, see also AAQ25452-25500 and AAQ30226-448.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      ·;

                                                                                                                                                                                                                                                                              ó;
                                                                                                                                     A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESED files AAQ75547-075798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) dispesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  This invention describes a novel DNA sequence (I) representing a promoter region having part or all of a specific base sequence. The invention also describes (1) a vector containing (I); (2) a cell transformed by the above vector; and (3) protein produced using (I). (I)

and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ752781) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression

The invention relates to preparation of a normalised, subdivided library of amplified cDNA from the coding regions of mRNA in a sample. The method livolves transfers transfersibility, with at least one CDNA primer of formula 5'-Conl-dTn2-Vn3-Nn4 to form first stand cDNA where Conl = any sequence of 1-100 nucleotides; dT = deoxythymidinyl; nZ is at least 1, n3 and and are both 0, or n3 is 1 and n4 is at least 1; followed by second strand cDNA synthesis using the first strand as template and a second cDNA primer of a similar formula, in the presence of DNA polymerase I (or strand cDNA primer of a similar formula, in the presence of DNA polymerase I (or famplification primers. Comparison of cDNA in the prepared library with a database (a computer-generated list of molecular weights of restricted DNA fragments of known sequence) is used to determine presence of an adatabase (a computer-generated list of molecular weights of restricted DNA fragments of known sequence) is used to determine presence of an computed adaignosis of disease). Surfaces (ching) having maplified cDNA stably immobilised on it, obtained by a similar method, with nucleic acid from the family (to identify new genes) and to detect differences in expression patterns between cells. The polypeptides C expressed by the libraries can be used for drug development. Sequences ANV1935 to ANV1946 represent primers used to exemplify the method of
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Preparation of normalised, subdivided cDNA libraries from mRNA - by reverse transcription and amplification, used to screen for new genes and interacting proteins, potential drugs, and for diagnosis
                                                                                                                                                                                                                                                                                                                                                                                                                                               Normalised, cDNA library; mRNA cloning; reverse transcription; immobilise; screening; hybridisation; nucleic acid amplification; expression pattern; drug development; PCR primer; RT-PCR; ss.

The invention can be used for genetic diagnosis of viral infections, especially human immune deficiency virus and heptitics B or C, particularly to detect memory minority genomes that are implicated in failure of antivixal therapy, so the method may make possible design of therapies customised for individual patients. The present nucleic acid sequence represents the VRA-MOT-11 DNA sequence that was used in the methods of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Baranowski E, Briones Llorente C, Domingo Solans E; Gomez Castilla J, Martin Ruiz-jarabo C;

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-075788) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) dispsting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Gaps

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoreaing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
    seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            Analysis of cDNA and gene expression - by amplification of mRNA followed by digestion with restriction enzymes

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    δ
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        ·.
                                                                                                                                                                                                                                          A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE) files AAQ75547-07598) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression rapidly and easily.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    A method for the analysis of cDNA comprises (a) preparing an aggregate of mRNAs and a plural type of labelled reverse transcription primers and a plural type of labelled reverse transcription primers (GENESEQ files AAQ7547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in

The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Gaps

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE files AAQ75547-Q7598) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes.                                                                                                                                                                                                                                                                                                                                                                     A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQYIS47-07579) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lames. The method can be used to analyse gene expression

The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Gaps

The present invention provides the protein and coding sequences of human phosphatichidylinosation. (PIDINS-3) Kinase 35. The sequences can be used in the treatment of cancer, haemopathy, HIV infection, development discorders, immunological diseases and inflammation. The present sequence
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     New human phosphatidylinositol-3 (PTDINS3) kinase 35 for diagnosing and treating malignant tumor, hemopathy, human immunodeficiency virus infection, immunological diseases and various inflammations
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     phosphatidylinositol-3 kinase 35; PTDINS-3 kinase 35; cancer; athy; development disorder; HIV infection; immunological disease;
          The present invention relates to the isolation of polypeptide-laminin B210.67, and the polypucleotide encoding it. Also described is the process for preparing the protein by DNA recombination. The polypeptide is useful for treating diseases such as embryo development teratogenesis. The present sequence for reverse transcriptase (RP)-PCR primer #1 is used with RT-PCR primer #1 is used with RT-PCR primer #2 (ABK12410) for isolating cDNA encoding polypeptide-laminin B210.67.
                                                                                                                                                                                                                       Gaps

The invention relates to systems for identification and characterisation of gene expression in one or more samples, comprising an identimer having a specific oligo-dT primer sequence, where the identimer comprises a a detectable marker at its 5' end. The system is useful for identifying any or all genes expressed in a given in vivo or in vitro RNA sample, as well as the relative differences in mRNA between 2 or more samples, where that are expressed at different levels between 2 or more samples, where that are expressed at different levels between 2 or more samples. The new system or method addresses limitations of prior methods by comprising compositions and systems that incorporate new strategies where molecular or biochemical assay compositions and systems are linked to DNA or RNA sequence databases for optimal resource efficiency in assaying gene cypression. The system has the following advantages over existing methods: (a) prior sequence information or clone library construction is continuation in addition to information or clone library construction is not needed to enable the assay; (b) provides immediate sequence information concerning changes or differences in mRNA level, to determine mRNA expression level and mRNA identification in one assay; (c) generates cDNA fragments from all mRNAs present in the genome of the organism under investigation by common molecular biology corganisms lacking significant genomic sequence in formation. The present convertion in the method of the present invention in the method of the present invention in the method of the present invention in the method of the invention in the income represents an oligo of primer used in the method of the

Garner HR,

```
A method for the analysis of cDNA comprises (a) preparing an aggregate of Gouble-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE) (iles AAQ75547-Q7759) and using the aggregate of mENAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Analysis of cDNA and gene expression - by amplification of mRNA
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      Analysis; gene expression; reverse transcription; primer; cDNA; aggregate; restriction enzyme; ss.

The computational methods (polymorphic marker prediction of ubiquitous simple sequences, POMPOUS, and Rep-X) are human genes, which can be used to understand, treat or eliminate genetic diseases, predispositions or adverse drug-treatment reactions. Examples of diseases linked to mucleotide repeats are Machado-Joseph, Haw River
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                syndrome, Huntington's disease, fragile-X syndrome, Fredreich's ataxis, myotonic dystrophy, hyperandrogenaemia, spinal and bulbar atrophy and spinocerebellar ataxia. The sequences presented in ABX7676-ABX80022 are the polymorphic repeats identified for a search of human ESTs.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The invention discloses a method for identifying a candidate polymorphic
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              Identifying a candidate polymorphic repeat within a coding sequence, for understanding or treating genetic disease, comprises detecting tandem repeats in a target coding sequence and scoring the repeats for

The method can be used to analyse gene expression rapidly and easily.
                                                             A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQV5547-Q7598) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in separate lanes. aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (CBRESEQ files AAQ7554-0.05798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction serzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lames. The method can be used to analyse gene expression rapidly and easily.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     ·

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GRNESEQ files AAQ75747-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression rapidly and easily.
                                                                                                                                                                                             A method for the analysis of CDNA comprises (a) preparing an aggregate of double-stranded CDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESED files AAQ75547-Q7798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded CDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE piles AAQ75547-075798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 Analysis of cDNA and gene expression - by amplification of mRNA followed by digestion with restriction enzymes
                                                                                                                                                     expression; reverse transcription; primer; cDNA;

A method for the analysis of CDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE pliles AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                               Analysis; gene expression; reverse transcription; primer; cDNA; aggregate; restriction enzyme; ss.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQV5547-07598) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) alectrophoresing the digested aggregate of cDNAs in seperate lames. The method can be used to analyse gene expression
                                                                               Gaps

A method for the analysis of cDNA comprises (a) preparing an anggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q7598) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoreasing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression

Identifying and characterizing gene expression in samples, for identifying mRNAs expressed at different levels, comprises employing an identimer having a oligo-dT primer of a specific sequence and a detectable marker at its 5' end ...

Disclosure; Page 11; 45pp; English.

The invention relates to systems for identification and characterisation of gene expression in one or more samples, comprising an identimer having detectable marker at its 5' end. The system is useful for identifying any or all genes expressed in a given in vivo or in vitro RNA sample, as well as the relative differences in mRNA between 2 or more samples, where that are expressed at different levels between 2 or more samples, where that are expressed at different levels between 2 or more samples. The new system or method addresses limitations of prior methods by comprising compositions and systems are all systems are molecular or biochemical assay compositions and systems are linked to DNA or RNA comments. sequence databases for optimal resource efficiency in assaying gene expression. The system has the following advantages over existing methods: (a) prior sequence information or clone library construction is

not needed to enable the assay; (b) provides immediate sequence information in addition to information concerning changes or differences in mRNA level, to determine mRNA expression level and mRNA identification in one assay; (c) generates cDNA fragments from all mRNAs present in the sample for subsequent investigation by common molecular biology the genome of the organism under investigation and can be employed in organisms lacking significant genomic sequence in formation. The present sequence is sequenced in the method of the security sequence.

Identifying and characterizing gene expression in samples, for identifying mRNAs expressed at different levels, comprises employing an identimer having a oligo-dT primer of a specific sequence and a detectable marker at its 5' end

Disclosure; Page 11; 45pp; English.

The invention relates to systems for identification and characterisation of gene expression in one or more samples, comprising an identimer having a specific oligo-dT primer sequence, where the identimer comprises a detectable marker at its 5' end. The system is useful for identifying any or all genes expressed in a given in vivo or in vitro RNA sample, as well as the relative differences in mRNA between 2 or more samples, where desired, for supporting discovery of new genes, and for identifying mRNAs that are expressed at different levels between 2 or more samples. The new system or method addresses limitations of prior methods by comprising compositions and systems that incorporate new strategies where molecular or biochemical assay compositions and systems are linked to DNA or RNA sequence databases for optimal resource efficiency in assaying gene expression. The system has the following advantages over existing methods: (a) prior sequence information or clone library construction is not needed to enable the assay; (b) provides immediate sequence information in addition to information concerning changes or differences

Preparation of normalised, subdivided cDNA libraries from mRNA - by reverse transcription and amplification, used to screen for new genes and interacting proteins, potential drugs, and for diagnosis

English. Example 1; Page 29; 71pp; The invention relates to preparation of a normalised, subdivided library of amplified cDNA from the coding regions of mRNA in a sample. The method involves reverse transcription, with at least one CDNA primer of formula 5.-Con1-dTn2-Vn3-Nn4 to form first stand cDNA where Con1 = any sequence of 1-100 nucleotides; dT = deoxythymidinyl; n2 is at least 1; n3 and n4 are both 0, or n3 is 1 and n4 is at least 1; followed by second cond and n4 are both 0, or n3 is 1 and n4 is at least 1; followed by second cond primer of a similar formula, in the presence of DNA polymerase I (or cond. PNA polymerase I (or cond. PNA polymerase I (or a database (a computer-spentated list of molecular weights of restricted a database (a computer-spentated list of molecular weights of restricted cond. PNA fragments of known sequence) is used to determine presence of an expressed protein in a cell, also to detect changes in such expression (particularly for diagnosis of disease). Surfaces (chip) having amplified cDNA stably immobilised on it, obtained by a similar method,

0 are used to screen for genes of a particular family, by hybridisation with nucleic acid from the family (to identify new genes) and to detect differences in expression patterns between cells. The polypeptides expressed by the libraries can be used for drug development.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         ö
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             The present invention provides the protein and coding sequences of human cyclophilin-40-12.54. The sequences can be used in the treatment of immunopathy and cancer. The present sequence is a PCR primer for the coding sequence of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Polypeptide-human cyclophilin-40-12.54 and polynucleotide for coding it

The present invention provides a method for identifying a set of extendible primers which can be used in the identification, typing and classification of genes. This can then be used to predict protein sequence and structure, in organ donation to match the organ with the receiver, and to identify bacteria in a sample. The method can be used to type the human leukocyte antigen genes (HLA) and 16s rRNA genes in particular.
                              classification of a nucleic acid of an organism, allele or gene such as class 1/2 HLA comprises identifying all possible nucleotide sequences
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                This invention describes novel contiguous and partially overlapping CDNA sequences and their encoded polypeptides, designated PAIS3, transcribed from human pancreatic tissue and which have cytostatic activity. The PAIS3 polymucleotides, proteins and antibodies are all useful in methods of detection. Detection of PAIS3 polymucleotide, antigens or anti-PAIS3 antibodies in a sample is indicative of pancreatic disease. PAIS3 antibodies (antagonists) can also be used in vivo for therapeutic use, e.g. treatment of pancreatic disease, tumours or metastases. Antisense PAIS3 polymucleotides can be used in gene
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Pancreatic disease; PA153; human; cytostatic; detection; antigen; anti-PA153; antagonist; therapy; treatment; tumour; metastasis; gene therapy; EST; expressed sequence tag; primer; ss.

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQTS547-C75789) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression rapidly and easily.
                         CDNA and gene expression - by amplification of mRNA digestion with restriction enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                          gene expression; reverse transcription; primer; cDNA;
restriction enzyme; ss.

                                                                                                                                                                                                                                                                                                                  A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) dispersing each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEG files AAQ75547-075798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) disesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mENAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q7798) and using the aggregate of mENAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                             Analysis; gene expression; reverse transcription; primer; cDNA; aggregate; restriction enzyme; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        expression; reverse transcription; primer; cDNA;
                                                                                                                                                         Reverse transcription primer used in cDNA analysis technique.

                and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digeting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  A method for the analysis of CDNA comprises (a) preparing an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESE) files AAQ7547-Q75789) and using the aggregate of mRNAs as themplate for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                                                                                                                                                                            Gaps
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Gaps
aggregate of double-stranded cDNAs by using an aggregate of mRNAs
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       by amplification of mRNA enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Analysis; gene expression; reverse transcription; primer; cDNA; aggregate; restriction enzyme; ss.

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEG files AAQ75547-075798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) dissting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression
                                                                                           Analysis of cDNA and gene expression - by amplification of mRNA followed by digestion with restriction enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Analysis of cDNA and gene expression - by amplification of mRNA followed by digestion with restriction enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          gene expression; reverse transcription; primer; cDNA;

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESED files AAQ7554-705798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) dispesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression

A method for the analysis of cDNA comprises (a) preparing an aggregate of double-stranded cDNAs by using an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESS) files AAQ75547-07559 and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in seperate lanes. The method can be used to analyse gene expression rapidly and easily.
                                                                         A method for the analysis of cDNA comprises (a) preparing an aggregate of mRNAs and a plural type of labelled reverse transcription primers (GENESEQ files AAQ75547-Q75798) and using the aggregate of mRNAs as the template for each reverse transcription primer; (b) digesting each of the prepared aggregates of the double-stranded cDNAs with restriction enzyme and; (c) electrophoresing the digested aggregate of cDNAs in separate lanes. The method can be used to analyse gene expression
         CDNA and gene expression - by amplification of mRNA digestion with restriction enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Analysis; gene expression; reverse transcription; primer; cDNA; aggregate; restriction enzyme; ss.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Analysis of cDNA and gene expression - by amplification of mRNA followed by digestion with restriction enzymes
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             Reverse transcription primer used in cDNA analysis technique.
                                                                                                                                                                                                                                                         Score 18.4; DB 1;
